

Walking and biking to the bus safely

**Safer City Streets Meeting | Buenos Aires |
04.10.2019**

Design Guidance

Global
Designing
Cities
Initiative

Transit facilities are the most efficient

Private Motor Vehicles
600–1,600/hour

Mixed Traffic With Frequent Buses
1,000–2,800/hour

Two-way Protected Bikeway
6,500–7,500/hour

Dedicated Transit Lanes
4,000–8,000/hour

Sidewalk
8,000–9,000/hour

On-street Transitway, Bus Or Rail
10,000–25,000/hour

Transit facilities are

up to **40** times

more efficient

The illustration shows the **hourly capacity of a 3 m-wide lane** (or equivalent width) by different modes at peak conditions with normal operations.

Efficiency is key, but it
cannot come at the cost
of **human life!**

We've been considering the
safety of **the transit
corridor**, but we should
expand to the **whole street
and its surroundings**

**Can people walk (or bike)
safely to transit?**

**Can people cross safely a
transit corridor?**

**Are speeds adapted to the
context?**

Everyone's transit journey begins with another mode

Understanding walking & biking access

Source: First Last Mile Strategic Plan, LA Metro

0/ Contextualize speeds

1/ Make the corridors permeable + create frequent opportunities to cross

2/ Design forgiving transit streets to pedestrians / give them space + time

3/ Reduce conflicts between bus and bikes

0/ Contextualize Speed

Considering the context

Demographics

Density

History and Culture

Mix of Uses and Destinations

Access and Mobility

Street Networks and Connectivity

Block Sizes

Road Safety

Ecosystems and Habitats

Natural Disasters

Geographic Features

Public Health

Contextual speed for transit

Considering the context

Context 1: Neighborhood Main Street

Context 2: Central Two-way Street

Context 3: Transit Mall

Considering the context

1/ Corridor permeability

Transit corridor project are an opportunity to reconnect the city

Avoid perpetuating or even creating barriers

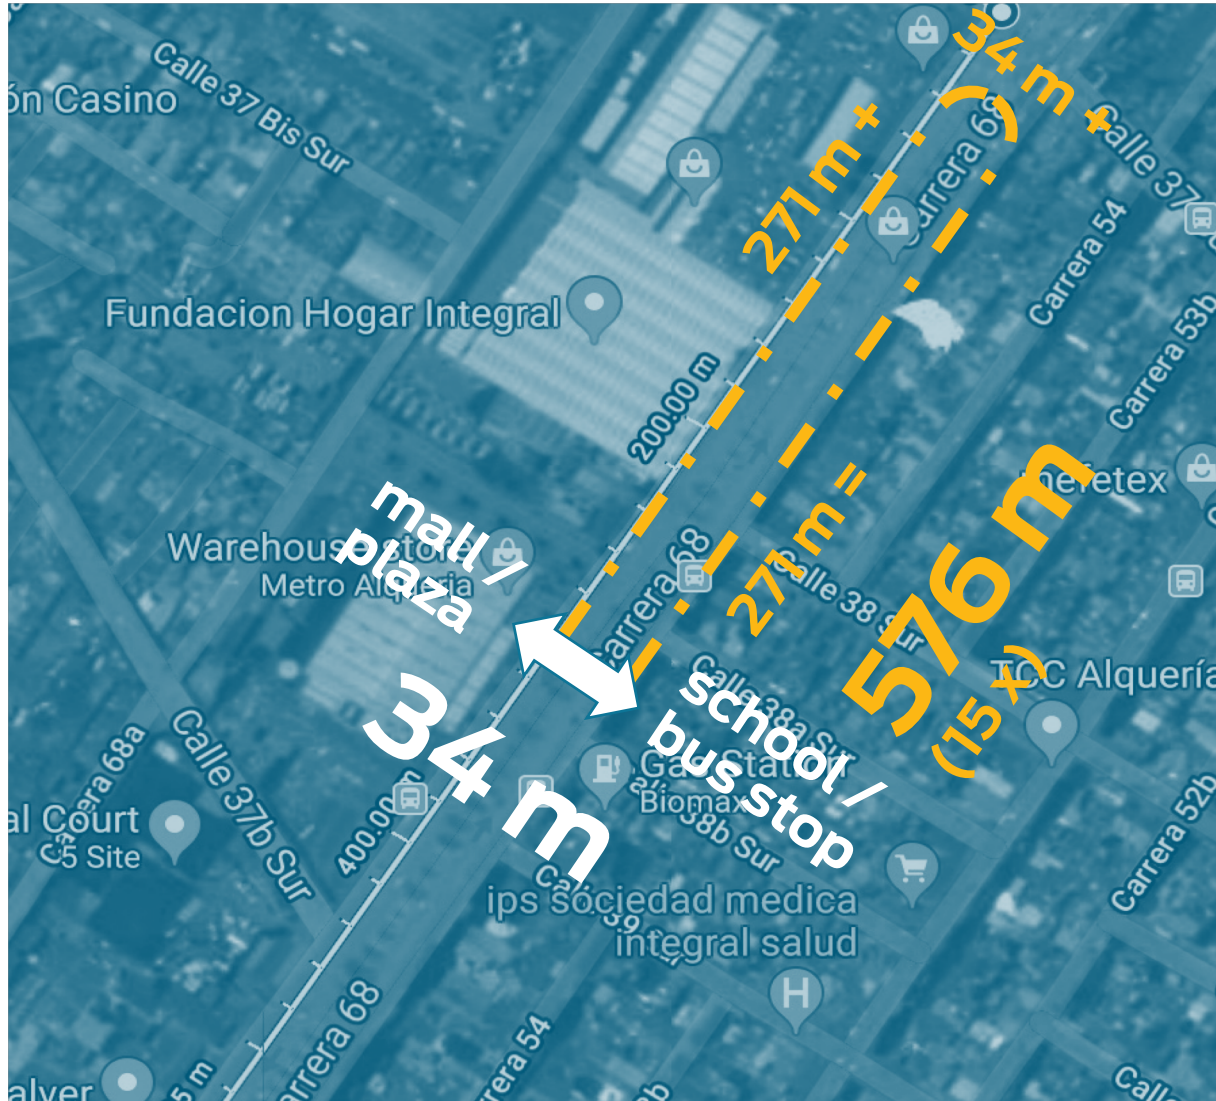

Provide opportunity to cross the street at grade and safely

Transit Corridors designed with 'blinders' on disconnect communities, and put people at risk

950 m

Walking speeds range from **0.3 m/s–1.75 m/s**

So if we take an average of **1 m/s:**

**576m = 576 seconds =
9.6 minutes**

**34m = 34 seconds =
0.5 minutes**

Crossing Distance

800 people/hr
crossing at
that location

Crossing distance

Safe, accessible crossings should be provided **every 80–100m**, and **at all legs** of an intersection, to ensure a connected walkable network.

Crossing distance

Safe, accessible crossings should be provided **every 80–100m**, and at **all legs** of an intersection, to ensure a connected walkable network.

96th Street and Broadway Intersection, NYC

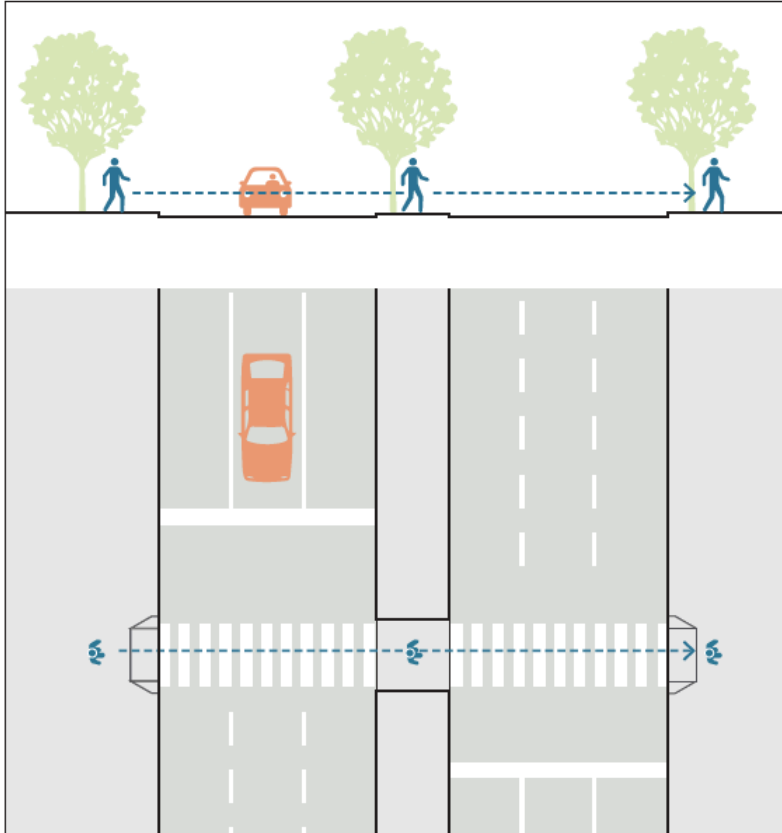

In early 2014, two fatalities occurred within 10 days at this intersection.

96th Street and Broadway Intersection, NYC

Grade separated crossings

Pedestrian bridges **unnecessarily** increase walking distances and times, take up valuable sidewalk space, and **cost 20+ times** the price of at-grade signalized crossings.

Crossings should be **AT-GRADE!**

**2/ Give pedestrians
space + time**

Refuge Islands

**Don't make
people choose
between a 25
tons bus and
speeding cars!**

Refuge islands

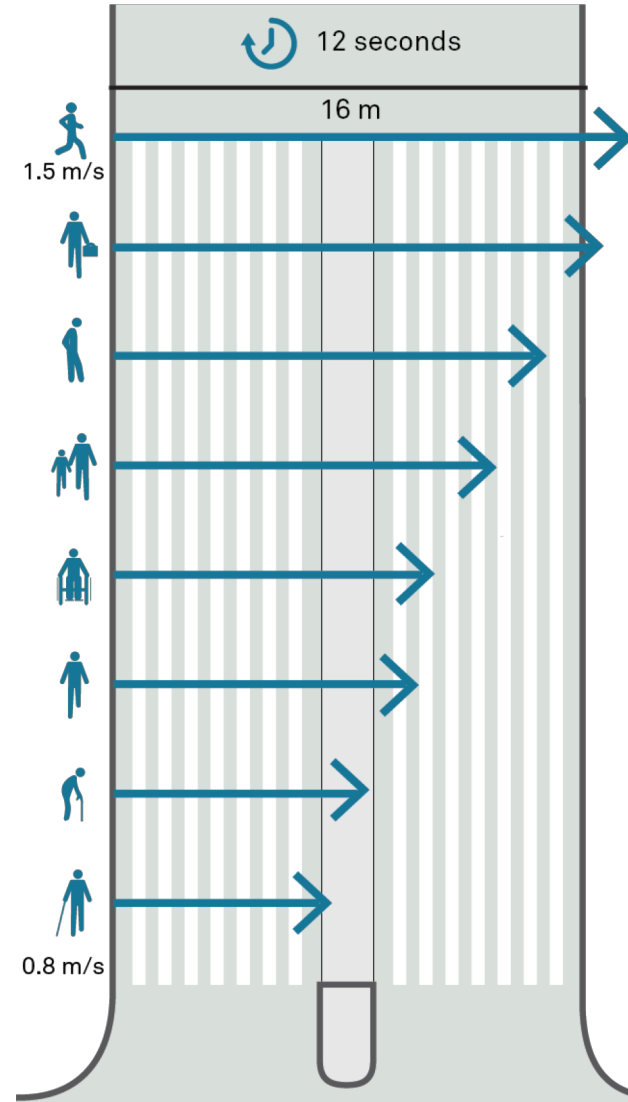

Provide refuge islands when a pedestrian has to cross 3+ lanes

Median tips

Pedestrians signals

The clearance time is generally based on a **1 m/s** walking speeds applied to the total crossing distance.

Many pedestrians walk below this speed:

- provide frequent refuge
- increase clearance time to allow for a **0.5 m/s** speed.

Pedestrians signals

So we should
give pedestrians

LESS DISTANCE
to cross...

And **MORE TIME**
to cross

**3/ Reduce conflicts
between bus and bikes**

Cyclists + Transit
